## 1 Introduction

MathsPIC ${ }^{1}$ is a small filter program for use with the excellent free $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ drawing engine ${ }^{2}$ (Nickalls, 1999a, 1999b; Syropoulos and Nickalls, 2000). MathsPIC parses a plain text input-file (the mathsPIC file), and generates a plain text output-file containing $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ and $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ commands which can then be $\mathrm{T}_{\mathrm{E}} \mathrm{Xed}$ (or LATEXed) in the usual way. Spaces and the comment $\%$ symbol are used in the same way as $\mathrm{T}_{\mathrm{E}} \mathrm{X}$, although unlike $\mathrm{T}_{\mathrm{E}} \mathrm{X}$, mathsPIC commands are not case-sensitive. $\mathrm{P}_{\mathrm{I}} \mathrm{CT} \mathrm{E}, \mathrm{T}_{\mathrm{E}} \mathrm{X}$ and $\mathrm{EAT}_{\mathrm{E}} \mathrm{X}$ commands can all be freely used in the mathsPIC file. MathsPIC also returns various parameter values in the output-file, e.g. angles, distances between points, center and radius of inscribed and exscribed circles, areas of triangles etc., since such values can be useful when making adjustments to a diagram.

The motivation for mathsPIC stems from the fact that, while $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ is an extremely versatile system for drawing figures, and offers the convenience and advantages of having the graphics code within the $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ document itself (e.g. printer-independence), it does require you to specify the coordinates of most points. This can make $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ quite awkward to use with complicated diagrams, particularly if several coordinates have to be re-calculated manually each time the diagram is adjusted. For example, suppose it is necessary to draw a triangle $A B C$ with $A B 5 \mathrm{~cm}, A C 3 \mathrm{~cm}$, and included angle $B A C 40$ degrees, together with its incircle. One such triangle is shown in Figure 1, and the $\mathrm{P}_{\mathrm{I}} \mathrm{CT} \mathrm{E} \mathrm{X}$ commands for drawing it are as follows (the units are in cm ).

Figure 1:

```
\put {$\bullet$} at 0 0 % draw point A
\put {$\bullet$} at 4.924039 0.8682409 % draw point B
\put {$\bullet$} at 1.928363 2.298133 % draw point C
\plot 0 0 4.924039 0.8682409 1.928363 2.298133 0 0/ % draw triangle
\circulararc 360 degrees from 3.008607 1.245238 center at 2.156815 1.245238
\put {$A$} at -0.5 0
\put {$B$} at 5.424039 . }868240
\put {$C$} at 1.428363 2.298133
```

Although point $A$ can be placed at the origin for convenience it is then necessary to resort to geometry and a calculator to determine points $B$ and $C$, since $A B, A C$, and the included angle are defined (see above). It is then necessary to recall the coordinates of all the points in order to write the \plot command. Finally, the \circulararc command requires even more geometry and calculation to figure out the radius of the incircle, the coordinates of its center, and the coordinates of the starting point of the arc-drawing routine. Furthermore, if the initial diagram is not a suitable shape or size, the calculator has to be used again for any adjustments. In practice, therefore, $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ requires a certain amount of planning and calculation for all but the simplest of diagrams.

MathsPIC overcomes all these difficulties by providing an environment for manipulating named points and scalar variables, which has the effect of making even complicated mathematical diagrams very easy to create. For example, the equivalent mathsPIC commands for drawing Figure 1 are as follows (the units are in cm as before).
point $(A)\{0,0\} \quad \%$ point $A$ at origin
point(B) $\{A, \operatorname{polar}(5,10 \mathrm{deg})\} \quad \%$ point $B 5 \mathrm{~cm}$ from $A ; A B$ slope 10 deg

[^0]```
point(C){A,polar(3,50 deg)} % point C 3 cm from A; BAC = 40 deg
drawPoint(ABC) % put $\bullet$ at points A B C
drawTriangle(ABC)
drawIncircle(ABC)
variable(d){0.5} % d = 0.5 cm
text($A$){A, shift(-d,0)} % label for A
text($B$){B, shift(d,0)} % label for B
text($C$){C, shift(-d,0)} % label for C
```

MathsPIC facilitates the drawing of $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ diagrams because not only does it allow points to be defined in terms of other points (relative addressing), but it also allows the use of scalar variables which can be manipulated mathematically (see Section 4.5). Consequently, diagrams can be constructed in an intuitive way, much as one might with a compass and ruler; for example, constructing a point at a certain position in order to allow some other point to be constructed, perhaps to draw a line to. In other words, mathsPIC offers the freedom to create 'hidden' points having a sort of scaffolding function. In particular, this facility allows diagrams to be constructed in such a way that they remain functionally connected even when points are moved (see Section 7.5). Files can also be input recursively (see Section 7.6). A significant feature of mathsPIC is that it allows TeX macros to be easily used within the mathsPIC file.

Note that mathsPIC can also be viewed as a handy tool for exploring elementary geometry since its show commands return the values of various parameters; for example, angles, the distance between points, coordinates of derived points, areas of triangles etc.

A PERL version of mathsPIC is currently being developed (Syropoulos and Nickalls, 2000), and should be available in 2001 (see Section 11).

## 2 Installing mathsPIC

CTAN:/tex-archive/graphics/pictex/mathspic/
mathsPIC can be downloaded from the above directory at CTAN (Comprehensive $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ Archive Network). See the file readme.txt. When installing $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ (see Section 9) I would recommend using the new $\mathrm{P}_{\mathrm{T}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ files by Andreas Schrell (1994), namely pictexwd.sty (for $\mathrm{LA}_{\mathrm{E}} \mathrm{X}$ users) and pictexwd.tex (for plain $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ users).

### 2.1 The program

```
mpic21.exe (rename to mathspic.exe)
```

The executable program mpic21.exe was compiled on an MS-DOS 6.2 platform. It is compatible with WINDOWS 9x, 2000, NT. For the purposes of this manual it is suggested that mpic21.exe be renamed to mathspic.exe. The executable program must be either in the same directory as the mathsPIC input-file, or in the directory path.

### 2.2 Optional utilities

```
show.com (a DOS textviewer)
clean.exe (a DOS tool for deleting comment lines)
```

These two files should be placed in the same directory as mathspic.exe. clean.exe is a program for removing all the commented lines from the output-file (see Section 3.2 for details). show. com is a simple textviewer which can be invoked using the /s switch (see Section 3.1.2 for details).

### 2.3 The manual

mpicm21.tex
mpicm21.dvi
mpicm21.ps

```
mpicm21.pdf
```

mpicm01.pic - mpicm16.pic

The 16 figure files mpicm01.pic-mpicm16.pic are input by mpicm21.tex. Note that all the mathsPIC files for these figures (mpicm01.m-mpicm16.m) are also included in the package-users are free to experiment with them as they wish.

### 2.4 Examples

The file examples is a collection of example figures and corresponding mathsPIC code.

## 3 Running mathsPIC

### 3.1 Command-line syntax

Assuming the .exe file has been renamed to mathspic.exe, then the minimum command-line instruction requires only the name of an input-file as follows.

```
mathspic inputfile
```

This will result in mathspic generating an output-file (in the same directory) with the same filename but with a .mt filename extension (see below for options), and a log-file (.mlg).

While mathsPIC is running, its progress is documented on the screen by a series of dots (one dot per program line). If an error is encounted then this is shown as an E instead of a dot, as follows.
. . . . . . . . . . . . . . . .E. . . .EE. . . . . . . . . .

### 3.1.1 Files

MathsPIC actions only the first two filenames (any additional filenames are ignored). Each filename must be isolated by at least one space. The order is important; the first filename is actioned as the inputfile (the mathsPIC file); the second filename (if present) is actioned as the outputfile.
mathspic inputfile outputfile
If the outputfile is not specified then mathsPIC will create an output-file having the same filename as the inputfile but with the filename extension .mt. For example, if you want an input-file called myinfile.abc to generate an output-file called myoutfile.xyz then use the following command.

```
mathspic myinfile.abc myoutfile.xyz
```

In practice, I find it convenient to use the filename extension .m for mathsPIC files (input-files), since I can then easily distinguish between the various files. Thus .m files are mathsPIC files (input-files), while .mt files are output $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ files containing $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands ready for $\mathrm{T}_{\mathrm{E}} \mathrm{Xing}$, and. mlg files are mathsPIC log-files.

### 3.1.2 Switches

Five switches are currently used (/? /h /help /b /s). Switches are not case-sensitive; they can be run together without intervening spaces; and they can be positioned anywhere, provided that they are separated by at least one space from any filenames. The switches are as follows.

> /? Help-shows all commands (also /h /help).
/b Error-beep. A beep is sounded if mathsPIC detects an error.
/s Screen view. Automatically shows the output-file using the free text-viewer show.com.
For example, the following command invokes both the error-beep and automatic viewing of the output-file by the default file-viewer show.com.

```
mathspic /b /s inputfile outputfile
```

### 3.2 Removing comment lines from the output-file

Once a diagram has been finalised, it is sometimes convenient to remove all the various commented lines from the final output-file, particularly if the file is a large one.

This can be easily done using the included clean.exe utility, which will strip out all lines starting with the double comment symbol \%\%. The /s switch can also be used with Clean.exe. Examples of the syntax are as follows.

```
clean.exe /?
clean.exe inputfilename
clean.exe /s inputfilename
clean.exe /s inputfilename outputfilename
```

If no output filename is supplied, then CLEAN.EXE will use the same filename but add the filename extension .mtc. For example, the following command will clean the output-file myfile.mt, generating the file myfile.mtc as the cleaned file, and then view the 'cleaned' output-file using show.com.

```
clean.exe /s myfile.mt
```

### 3.3 Batch processing

In addition to running the program from the command-line, mathsPIC can also be run from a batch-file (some familiarity with the MS-DOS batch-file language is assumed; note that the batch-files need to be tailored to the particular command-line sequence.) For example, the following command line with five parameters (two switches and three filenames)

```
mathspic /b /s testpic.m testpic.mt testpic.dvi
```

will be executed by the following MS-DOS batch-file (written for the $\mathrm{EmT}_{\mathrm{E}} \mathrm{X}^{3}$ implementation of $\mathrm{EAT}_{\mathrm{E}} \mathrm{X}$ for PCs using MS-DOS), which first runs mathsPIC on the input-file testpic.m; then calls $\mathrm{IAT}_{\mathrm{E}} \mathrm{A}_{\varepsilon}$ to process the output-file; and finally calls the $\mathrm{EmT}_{\mathrm{E}} \mathrm{X}$ screen viewer dviscrs.exe (via vs.bat) to view the file testpic.dvi (\%5).

REM mathsPIC.bat (MS-DOS 6.0 and greater)
@ECHO OFF
mathspic.exe $\% 1 \% 2 \% 3 \% 4 \%$
CALL latex2e \%4
CALL vs.bat /s3 \%5
Note that care needs to be taken to make sure that the parameters used in the batch-file correspond to the command-line parameters. For example, if the two switches are run together without a space (e.g. /b/s) they will be perceived by MS-DOS as a single entity, in which case the .dvi file would be represented by $\% 4$ in the batch-file instead of $\% 5$. For example, the following four-parameter commandline
mathspic /b/s testpic.m testpic.mt testpic.dvi
would require the following MS-DOS batch-file.

```
@ECHO OFF
mathspic.exe %1 %2 %3 %4
CALL latex2e.bat %3
CALL vs.bat /s3 %4
```

[^1]As a final example (again based on the EmTEX implementation), suppose you wish to use your own text-viewer (say, myTextViewer.exe) to view the output-file, with the /b switch (enables errorbeep), and have conditional branching-i.e. have the option to either (a) quit (select the ' N ' option) and return to the text-editor after viewing the output-file, or (b) proceed (select the ' Y ' option) and process the output-file testpic.mt (\%3) and then view the .dvi file (\%4). In this example, the following four-parameter command-line

```
mathspic /b testpic.m testpic.mt testpic.dvi
```

could be run using the following batch-file.

```
REM mPIC.bat (MS-DOS 6.0 and greater)
@ECHO OFF
mathspic.exe %1 %2 %3 %4
CALL myTextViewer.exe %3
CHOICE /C:YN View figure?:
IF ERRORLEVEL 1 IF NOT ERRORLEVEL 2 GOTO yes
GOTO no
:yes
CALL latex2e %3
CALL vs.bat /s3 %4
:no
```

## 4 The mathsPIC file and script

The idea underlying the mathsPIC file (input-file) is that it should be able to contain everything required to generate the proposed figure (i.e. all mathsPIC commands, comments, $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ and $\mathrm{E}_{\mathrm{E}} \mathrm{X}$ commands including headers and footers, $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{EX}}$ commands, as well as lines to be copied verbatim) so that the output-file can be immediately $\mathrm{T}_{\mathrm{E}} \mathrm{Xed}$ to generate the graphic. Some general points relating to the mathsPIC file are as follows.

- mathsPIC commands are not prefixed by backslashes. They are therefore easily distinguished from $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ and $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands.
- Each mathsPIC command must be on a separate line. This is because mathsPIC frequently adds data to the end of a line in the output-file (see below).
- As with $T_{E X} X$, spaces can be used to enhance readability. This is particularly useful when writing lists of points. For example the command drawpoint (a1a22a34a4) can be made easier to read by writing it as drawpoint(a1 a22 a34 a4).
- mathsPIC commands and point-names are not case sensitive. This allows the user to customise the commands to enhance readability. Thus the command drawpoint can be written as drawPoint or DrawPoint etc.
- Delimiters have a hierarchical structure as follows:

Curved brackets contain the primary argument; e.g. showPoint (A)
Braces contain required supporting arguments; e.g. point (A) $\{5,6\}$
Square brackets contain optional arguments; e.g. point (p3) \{a, shift (1,2)\}[circle, 5]

- Logically distinct groups within brackets must be separated by commas. e.g. point (B2) \{A, polar (3,40deg) [circle, 5]
- Comments are prefixed by the $\%$ symbol in the usual way. Lines having a leading $\%$ symbol are copied verbatim through to the output-file.
- Lines having a leading backslash command (i.e. where there is no inter-word space immediately following the backslash, e.g. \setdashes or \begin\{document\}) are copied verbatim through to } the output-file. Consequently, all $\mathrm{T}_{\mathrm{E}} \mathrm{X}, \mathrm{A}_{\mathrm{E}} \mathrm{X}$ and $\mathrm{P}_{\mathrm{I}} \mathrm{CTEX}_{\mathrm{E}}$ commands can be used in the normal way providing the command is restricted to a single line. However, if such commands do run on to the subsequent lines, these lines will need to be prevented from being processed as mathsPIC commands, by prefixing them with $\_{\sqcup}$ (see below) - unless of course they also start with a backslash command (see Sections 4.1 and 4.2).
- Lines having a leading $\rangle_{\sqcup}$ (i.e. where the $\backslash$ is followed immediately by one or more inter-word spaces $\sqcup$ e.g. $\backslash 25.316 .8$ ) are copied verbatim through to the output-file without the leading backslash.
- Data-files containing mathsPIC commands can be input using the inputfile command. Files can also be input verbatim using the inputfile* command (useful for inputting files containing only $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands and/or coordinate data; for example, a list of data points as part of a $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ $\backslash$ plot command)-see example in Section 7.6.1

## $4.1 \quad \mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands

Note that $\mathrm{P}_{\mathrm{T}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands can only be used within the \beginpicture ... \endpicture environment, as described in the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ Manual ${ }^{4}$ (Wichura, 1992).

Most $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands are short one-line commands starting with a leading backslash. Such commands can be used in the normal way as mathsPIC will automatically copy lines starting with a backslash command unchanged through into the output-file (.mt file). For example, drawing with dashed lines is enabled using the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \setdashes command, and this would be expressed in the mathsPIC file as follows.

```
\setdashes
```

However, some $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands are very long. It is therefore sometimes necessary to have the initial part of a $\mathrm{P}_{\mathrm{I}} \mathrm{PT}_{\mathrm{E}} \mathrm{X}$ command on one line, with the rest of the command continuing onto the next line, such that the second and subsequent lines may well not have a leading backslash command. In order to protect such subsequent lines from being processed as mathsPIC commands, they must be protected by a leading backslash followed by one or more spaces (e.g. $\_{\sqcup} \ldots$ ) as this instruction tells mathsPIC to copy the rest of the line unchanged (without the leading backslash) through into the output-file. For example, the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ code for plotting data-points for a curve could be spread across several lines in the mathsPIC file as follows.

```
\setquadratic
\plot 1.15 -0.67
\ 1.25 0.02
\ 1.35 1.24
\ 1.45 3.13/
\setlinear
```

When these commands are processed by mathsPIC, they will appear in the output $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ file (.mt file) as follows.

```
\setquadratic
```

\plot 1.15 -0.67
$1.25 \quad 0.02$
$1.35 \quad 1.24$
1.45 3.13 /
\setlinear

[^2]
## 4.2 $\quad \mathrm{T}_{\mathrm{E}} \mathrm{X}$ and $\mathrm{HT}_{\mathrm{E}} \mathrm{X}$ commands

### 4.2.1 Headers and footers

It is particularly useful to include in the mathsPIC file any r$L_{E}T_{E}X$headersandfooterswhichwouldotherwisehavetobeaddedmanuallytotheoutput-filebefore$\mathrm{IAT}_{\mathrm{E}}\mathrm{Xing}$thefile.Forexample,whenusing${}^{2}\mathrm{~T}_{\mathrm{E}}\mathrm{X}$atypicalformatforamathsPICfilemightbeasfollows(notethatinthisexampleAndreasSchrell'sstyleoptionpictexwd.styisused-seeSection9.2).\documentclass[a4paper]\{article\}\usepackage\{pictexwd\}\begin\{document\}}\beginpicture...\endpicture\end\{document\}}Forusersofplain$\mathrm{T}_{\mathrm{E}}\mathrm{X}$atypicalformatmightbeasfollows(seeSection9).undefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefined

```
\input latexpic.tex
\input pictexwd.tex
\font\tiny=cmr5 %% used for drawing lines
\font\large=cmr12 %% used for drawing thicklines
\beginpicture
...
\endpicture
\bye
```

If it is necessary (or just simply convenient) to extend a $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ or $\mathrm{LA}_{\mathrm{E}} \mathrm{X}$ command across several lines, then each additional line must be protected within the mathsPIC file using a leading $\backslash_{\sqcup} .$. sequence (see Section 4.1) unless a line actually starts with a $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ command. A typical example is the following macro (used in Figure 9) which defines a 'display' maths formula. The macro is split across several lines, as follows.

```
\newcommand{\formula}{%
\ $\displaystyle \sum_{p\ge0} \Delta_{jp} z^{(p+1)}$%
\ }%
text(\formula){B1}
```

Note that when using $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ or $\mathrm{IA}_{\mathrm{E}} \mathrm{X}$ commands within the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ picture environment, it is very important to include the comment $\%$ symbol at the end of such lines, to prevent $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ accumulating additional space characters from the ends of non- $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{C}$ commands, since otherwise $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ incorporates such space characters into the horizontal distance used for representing $x$-coordinates, with the effect that all subsequent picture elements may be displaced slightly to the right.

### 4.2.2 Other TEX commands

A very useful command is the \typeout $\left\}\right.$ command, which will make $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ print comments to the screen while the output-file is being processed. For example, the following commands in the mathsPIC file will print a message to the screen just before processing a data-file for a curve.

```
\typeout{processing the data-file now}%
inputfile*(curve.dat)
```

This command is also useful is when a file is input several times in a loop using the mathsPIC inputFile\{..\}[] command. In such cases it is quite useful to include the line \typeout $\{\ldots$. . $\%$ at the beginning of the file being input, as this results in $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ printing ... to the screen each time the file is input.

Note the importance of including the comment \% symbol at the end of the line when the \typeout $\} \%$ command is used within the $\mathrm{P}_{\mathrm{I}} \mathrm{T}_{\mathrm{E}} \mathrm{X}$ picture environment.

### 4.3 The plotting area

### 4.3.1 Axes

When drawing a new figure it is often useful to have a graduated ruled frame to guide placement of picture elements. This task is greatly simplified by using mathsPIC's one-line paper command, which has optional axes and ticks parameters ${ }^{5}$. The axes-codes used in the axes() option are L (Left), R (Right), T (Top), B (Bottom), X (X-axis), Y (Y-axis). For example, the following paper command generates a drawing area $5 \mathrm{~cm} \times 5 \mathrm{~cm}$ with a ruled frame on four sides as shown in Figure 2a.
paper\{units $(\mathrm{mm})$, xrange $(0,50)$, yrange $(0,50)$, axes (LRTB) ,ticks $(10,10)\}$
This particular paper command is converted by mathsPIC into the following $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ code in the output-file (.mt file).

```
\setcoordinatesystem units <1mm,1mm>
\setplotarea x from 0 to 50, y from 0 to 50
\axis left ticks numbered from 0 to 50 by 10 /
\axis right ticks numbered from 0 to 50 by 10 /
\axis top ticks numbered from 0 to 50 by 10 /
\axis bottom ticks numbered from 0 to 50 by 10 /
```

Figure 2:
For graphs it is more usual for the axes to be centered on the origin $(0,0)$, and this is provided for by the XY options. For example, Figure 2b was generated using the following paper command,
paper\{units (cm), xrange ( $-2,3$ ), yrange ( $-2,3$ ), axes (XY), ticks $(1,1)\}$

[^3]which is converted by mathsPIC into the following $\mathrm{P}_{\mathrm{T}} \mathrm{T}_{\mathrm{E}} \mathrm{X}$ code in the output-file.

```
\setcoordinatesystem units <1cm, 1cm>
\setplotarea x from -2 to 3, y from -2 to 3
\axis left shiftedto x=0 ticks numbered from -2 to -1 by 1
    from 1 to 3 by 1 /
\axis bottom shiftedto y=0 ticks numbered from -2 to -1 by 1
    from 1 to 3 by 1 /
```

The tick-marks associated with an axis can be prevented by using a ${ }^{*}$ after the axes-code (e.g. axis (LBT*R*) gives four axes but generates tick-marks only on the Left and Bottom axes). Note that any combination of axes-codes can be used. For example, the options ...axes (LRTBX*Y*), ticks (10, 10) will generate a rectangular axes frame (with ticks) containing the $X Y$ axes (without ticks).

The line-thickness of axes and tick-marks is controlled by the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \linethickness command (see Section 4.6.1, and also Figure 14).

Once the figure is finished, then the frame or axes can be easily adjusted or even removed. The figure can also be scaled in size simply by altering the units parameters. For example, the option units ( $3 \mathrm{~cm}, 1 \mathrm{~cm}$ ) will generate an $X$-axis having three times the scale as the $Y$-axis (see Figure 14). If complicated or more demanding axis configurations are required, then the $\mathrm{P}_{\mathrm{I}} \mathrm{CT} \mathrm{EX}$ Manual (see Section 9.5) will need to be consulted. See also Section 8 for details on positioning figures within IAT $_{E} \mathrm{X}$ documents.

### 4.3.2 Units

In addition to the usual units mm, cm, and pt, $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ accomodates the other six units used by $\mathrm{T}_{\mathrm{E}} \mathrm{X}^{6}$, and also uses the same two-letter codes, namely pc (pica), in (inch), bp (big point), dd (didot), cc (cicero), sp (scaled point). The available units thus enbrace the Metric system (mm, cm), the Didot system (didot, cicero), and the UK system (point, big point, pica, inch).

Note that if only one unit is indicated in the units option, then mathsPIC uses the same unit for both the $x$ and $y$ axes. Thus the option units ( mm ) in the paper command is translated by mathsPIC into the following $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ command in the output-file.
\setcoordinatesystem units <1mm,1mm>
Note that variables can also be used to control the $x$ and $y$ units, as shown in the following example, where the radius ( $r$ ) and the distance ( $s$ ) between the label $A$ and its point-location are fixed irrespective of scaling (i.e. with changes in the value of $u$ ) by dividing the relevant variables by the scaling value $u$.

```
variable(u){1.5}
paper{units(u mm), xrange(0,100), yrange(0,100)}
variable(r){2}
variable*(r){r, divide(u)}
point(A){30,20}[circle,r]
variable(s){4}
variable*(s){s, divide(u)
text($A$){A, shift(-s,s)}
```

If different scales are required (most commonly when drawing curves and equations-see Figure 14) then both need to be specified in the mathsPIC units option. For example, if units of 1 cm and 2 mm are required for the $x$ and $y$ axes respectively, then this will be implemented by the mathsPIC command units ( $1 \mathrm{~cm}, 2 \mathrm{~mm}$ ). However, when the $x$ and $y$ scales are different strange effects can occasionally occur, particularly if drawing ellipses or circular arcs. In view of this mathsPIC writes a warning note to the output-file and log-file when different units are being used. The drawing of complete circles will only

[^4]be affected if the $x$-units is changed, since the mathsPIC starts the arc at a location having the same $y$-coordinate as that of the center. In general users are therefore recommended to avoid using different $x$ and $y$ units in the paper command if at all possible.

### 4.3.3 Tick-marks

It is recommended that integers are used with the ticks option, since $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ sometimes gives unpredictable results if decimals are used with the xrange and yrange options in conjunction with the ticks option. In general $\mathrm{P}_{\mathrm{T}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ gives more pleasing axes if integers are used throughout the paper command.

### 4.4 Points

Each point is associated with a point-name which is defined using the point command. For example, the following command allocates the point-name $A$ to the coordinates $(5,7)$.
point(A) $\{5,7\}$
Once defined, points can be referred to by name. Consequently, points can be defined in relation to other points or lines simply by using point-names, as shown by the following commands.

```
point(C){midpoint(AB)}
point(E){intersection(AB,CD)}
point(J){Q, rotate(P, 25 deg)} %% J = Q rotated about P by 25 deg
```

Points are interpreted according to their grouping and context. Thus two points represent either a line or its Pythagorean length. For example, the command drawCircle ( $\mathrm{P}, \mathrm{AB}$ ) means draw a circle, center $P$ with radius the length of line $A B$. A group of three points represents either a triangle, an angle, or a line, depending on the circumstances.

### 4.4.1 Point-name

A point-name must begin with a single letter, and may have up to a maximum of two following digits. The following are valid point-names: $A, B, C 3, d 45$. Since mathsPIC is not case sensitive the points $d 45$ and $D 45$ are regarded as being the same point. Point-names can be either separated by spaces, or simply run together.

Sometimes it is necessary to re-allocate new coordinates to an existing point-name, in which case the point* command is used. This is often used during recursive operations whereby the mathsPIC file inputs another file (using the inputfile command) containing commands which alter the value of pre-existing points. For example, the following command increments the $x$-coordinate of point $A$ by 5 units.

```
point*(A){A, shift(5,0)}
```

### 4.4.2 Point-symbol

The default point-symbol is - (\$ $\$$ bullet $\$$ ). However, mathsPIC allows the optional use of any $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ character or string of characters to represent a particular point, by including it in a following square bracket. For example, the point $A(5,10)$ can be represented by the $\triangle$ symbol by defining it as follows.

```
point(A){5,10}[$\triangle$]
```

The default point-symbol can also be changed to any $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ character or string of characters by using the mathsPIC PointSymbol command, and putting this command before any relevant point commands, since the PointSymbol command only influences subsequent point commands. For example, the character $\odot(\$ \backslash o d o t \$)$ can be made the new global point-symbol by using the command PointSymbol ( $\$ \backslash$ odot $\$$ ). The original default point-symbol ( $\bullet$ ) can be reinstituted (reset) using the command PointSymbol(default). The point-symbol is drawn at the point-location using the drawPoint command; for example, drawPoint (A), or drawPoint (ABCD).

Since most $T_{E} X$ characters and symbols are typeset asymmetrically in relation to the baseline, they will not be positioned symmetrically over a point-location. Most characters are therefore not ideal for use as point-symbols, as they generally require some slight adjustment in order to position them symmetrically. In view of this, Table 1 lists those $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ characters which are particularly suitable, since they are automatically positioned by $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ symmetrically with respect to a point-location (for example the $\odot$ character $\$ \backslash \operatorname{odot} \$)$, and are therefore ideal for use with $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$.

### 4.4.3 Line-free zone

When lines are drawn to a point, the line will (unless otherwise instructed) extend to the point-location. However, this can be prevented by allocating an optional circular line-free zone to a point by specifying the line-free radius in a following square bracket. For example, lines to a $\triangle$ symbol at point $A$ can be prevented from being drawn through the triangle to its center by allocating a 5 unit line-free zone to the point, as follows.

```
point(A){3,10}[$\triangle$,5]
```

If only the line-free radius is to be specified then a preceding comma must be used (e.g. [,10]). For example the following mathsPIC command would change the line-free radius associated with point $A$ to 10 units.

```
point*(A) {A}[,10]
```

Table 1 gives a list of useful point-symbols which $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ places symmetrically over a point-location (note that $\$ \backslash \operatorname{Box} \$$ and $\$ \backslash$ Diamond $\$$ are not placed symmetrically over a point location, but $\$ \backslash$ square $\$$ and $\$ \backslash l o z e n g e \$$ are). Other useful symbols are available from the textcomp fonts ${ }^{7}$. For example, the following commands will draw lines between points ABC , such that the lines just touch the edge of the $\odot$ point-symbol (line-free radius 1.2 mm ; 10pt font).

```
point(A){1,1}[$\odot$, 1.2]
point(B){2,2}[$\odot$, 1.2]
point(C) {1, 3} [$\odot$, 1.2]
drawline(ABC)
```

It is often useful to adjust the line-free radius associated with a particular point before drawing lines or arrows to it, in order to optimise the distance between an object centered at the point and the line or arrow. For example, one can use the point* command to set a line-free radius of 2 units for a pre-existing point $(P)$, as follows.
point* (P) \{P\}[,2]
By way of illustration, this command is used in drawing Figure 3 where arrows are being drawn from various directions ( $B, S$ ) to a text box centered on point $P \odot$ (the code is shown below as mpicm03a.m). By setting the line-free radius (dashed circles) associated with point $P$ before drawing each particular arrow, one can easily adjust and optimise the distance between the arrowhead and the text box.

```
%% mpicm03a.m (Figure 3)
\beginpicture
paper{units(cm), xrange (0,6),yrange(0,3), axes(LBT*R*),ticks(1,1)}
point(P) {4,2}[$\odot$]
point(B) {2,0.5}
point(S){1,2}
drawPoint(PBS)
\setdashes
```

[^5]Table 1: Useful point-symbols and their radii for $10-12 \mathrm{pt}$ fonts.

```
\inboundscheckon %% restrict circles to drawing area
drawcircle(P,1)
drawcircle(P,2)
\setsolid
point*(P){P}[,1] %% set line-free radius of P to 1 cm
drawArrow(BP)
point*(P){P}[,2]
drawArrow(SP) %% draw arrow from S (side)
text($S$){S, shift(-0.4,0)}
text($B$){B, shift(-0.4,0)}
text(\textsc{p}){P, shift (0.3,0)}
\newcommand{\textbox}{\fbox{text\hspace{17mm}box}}%
text(\textbox){P}
\endpicture
```

Of course, sometimes it is convenient just to draw the arrows a certain length from one point towards another point. For example, in Figure 3, the two point* commands and the two drawArrow commands

Figure 3:
could all be replaced by the following two commands using the [ ] option to indicate the length of the arrow.
drawArrow (SP) [1] \%\% draw arrow 1 unit from point A towards P
drawArrow (BP) [1.5] \%\% draw arrow 1.5 units from point B towards P

### 4.4.4 Order of points

The order of points in mathsPIC commands is sometimes significant. For example, the command point (D) $\{$ PointOnLine $(A B, 23)\}$ defines the point $D$ as being 23 units from $A$ in the direction of $B$.

### 4.4.5 Number of points

The maximum combined number of named points and variables which can be used is currently set by default at 50 . The total array space for points and variables can be increased by using the mathsPIC PointNumber () command. For example, array space for a total of 75 points/variables would be allocated by the command PointNumber (75).

If the combined point/variable allocation is exceeded, then a so-called 'fatal error' arises and the program terminates. The following example (from an output-file) documents a fatal error which occured while the program was trying to define a new point $Z_{3}$.
$\% \%$ *** point (Z3) $\{\mathrm{P}, \operatorname{shift}(2,5)\}$
$\% \%$... FATAL ERROR: points used exceed allocation
$\% \%$... use the PointNumber() command to increase allocation

### 4.5 Scalar variables

Numeric scalar variables are defined using the variable(name) \{value\} command. The value in the braces can be either a numeric (e.g. 4.32; 2.6E-2), a variable name (e.g. r3), or two points (e.g. ABmeaning the Pythagorean distance between the two points $A, B$. Thus the command variable (r3) \{20\} allocates 20 to the variable r3, which could then be used, for example, as the radius in the circle command drawcircle (C3,r3). New values can be re-allocated to existing variable-names using the variable* command.

However, one must be careful not to mistake variables for points, and vice versa, since they both have the same name structure. When both are necessary, using upper case for points and lower case for variables is a convenient strategy. If you inadvertently use a point instead of a variable mathsPIC will generate an appropriate error message (see the last example in Section 5.1).

### 4.5.1 Arithmetic

Variables can be manipulated using the commands advance, multiply, divide and mod. The format is similar to that of the point commands. Thus the command variable(a1) \{a, advance(-r3)\} makes the variable a1 assume the value a-r3 (i.e. $a_{1}=a-r_{3}$ ). Note that although mathsPIC allows the use
of the negative sign with variables (e.g. $-5.34,-r 3$ ), the positive sign is not allowed. Examples of valid variable commands are given in Section 6.

### 4.5.2 Scientific notation

When numbers are either very small or very big they are generally written using the usual computer 'E' format of so-called 'scientific notation', for example, 1.243E-9 etc. mathsPIC allows the use of scientific notation in commands wherever decimals are normally allowed, as follows.

```
variable(p2){3.78E3}
point(Z3){J,shift(1.3E-1,6)}
```

Unfortunately, $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ does not process numeric values in scientific notation, and will generate an error message whenever it finds the letter E as part of a number. Consequently mathsPIC converts all numbers which appear within $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}}$ commands in the output-file into conventional decimal format (place-value notation). If the value is less than $1.0 \mathrm{E}-7$ ( 0.0000001 ) then mathsPIC simply converts the value to zero.

However, since this convertion requires additional checking, mathsPIC does not bother to do this when it outputs data to the end of a commented line. For example, in the following extract from an output-file the variables $s_{4}$ and $s_{5}$ appear in scientific notation when in commented lines, but in decimal notation in the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X} \backslash$ put. . . commands (see the line for point $J_{45}$ ). Note also that in this example the $y$-coordinate of $J_{45}$ appears as zero in the \put. . . command (since s5 is less than 0.0000001 ), but as $2.3 \mathrm{E}-8$ in the \%\%variable (s5) \{... line.

```
%% variable(r){23} ( 23 )
%% variable(s1){r,divide(100000)} ( . 00023 )
%% variable(s2){r,divide(1000000)} (.000023 )
%% variable(s3){r,divide(10000000)} ( .0000023 )
%% variable(s4){r,divide(100000000)} ( 2.3E-7 )
%% variable(s5){r,divide(1000000000)} ( 2.3E-8 )
%% point(J12){s1,s2}
%% point(J23){s2,s3}
%% point(J34){s3,s4}
%% point(J45){s4,s5}
%% drawpoint(J12 J23 J34 J45)
\put {$\bullet$} at .00023 .000023 %% J12
\put {$\bullet$} at . }000023.0000023 %% J2
\put {$\bullet$} at .0000023 .00000023 %% J34
\put {$\bullet$} at .00000023 0 %% J45
```

### 4.6 Lines

mathsPIC draws lines using its drawLine and drawThickline commands. For example, a line from $P_{1}$ to $P_{2}$ is drawn with the command drawLine (P1P2). If a line is to be drawn through several points (say, $J_{1}, J_{2}, J_{3}, J_{4}, J_{5}$ ) and can be drawn without 'lifting the pen', then this can be achieved using the single mathsPIC command drawLine(J1J2J3J4J5). Several unconnected lines can also be drawn using one command by separating each line segment with a comma; for example, drawLine(J1J2, J3J4J5, J1J3).

A line can also be drawn a specified distance from one point towards (or away from) another point, using the square-bracket option. For example, the following command draws a line a distance $d$ units from point $A$ towards point $B$.

```
drawline(AB) [d]
```

Note that in this particular command the order of the points $A B$ and the sign of the distance [d] are important. For example, the following command will draw a line a distance $d$ units from point $B$ away from point $A$.

```
drawline(BA) [-d]
```

Since the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \putrule command for drawing horizontal or vertical lines is much more memory efficient than the \plot command, mathsPIC automatically invokes the \putrule command for horizontal and vertical lines (see also Pictex2.sty in Section 9.3).

However, there are some occasions when it is necessary to draw using the $\backslash \mathrm{plot}$ command even for horizontal and vertical lines (eg. when using \setdots with larger than usual dots), in which case the drawline* command (disables the use of $\backslash$ putrule) should be used.

### 4.6.1 Line thickness

$\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{d}$ draws lines using two different methods depending on whether the lines are (a) horizontal or vertical, (b) any other orientation. These two groups use different commands for controlling linethickness, as follows.

## Horizontal and vertical lines (rules)

Horizontal and vertical lines are drawn using the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \putrule command ${ }^{8}$ and consequently the thickness of such lines is controlled by the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \linethickness command (the default line-thickness is 0.4 pt ). For example, the following $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ command changes the thickness to 1 pt .

```
\linethickness=1pt
```

The \linethickness command is also useful for adjusting the thickness of graph axes, tick marks. For example, the following commands are used in the code for Figure 14 to draw thick axes.

```
\linethickness=2pt
paper{units(mm),xrange(0,50),yrange(0,50),axes(XY)}
\linethickness=0.4pt %% reset to default
```

Note also that the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \linethickness command can also be reset to its default value ( 0.4 pt ) by the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \normalgraphs command, which resets all $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ graph-drawing parameters to their default values including \linethickness (see Section 6.3).

## Other lines and curves

All other lines (non-horizontal non-vertical) and curves are drawn using the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X} \backslash \mathrm{plot}$ command which draws a continuous line of dots. Consequently the thickness of these lines is controlled by the size of the dot, which is defined using the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \setplotsymbol command, the default size of dot being $\left\{\backslash\right.$ tiny .\}. Larger dots therefore generate thicker lines. For example, the following $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ command sets the dot to a larger size.

```
\setplotsymbol({\Large .})
```

The mathsPIC drawLine command uses the current dot size. However, the mathsPIC drawThickline command uses the \large dot size, but then resets the dot size to \tiny. For example, the commands

```
point(A){5,5}
point(B) {10,10}
drawThickline(AB)
```

will result in the following code in the output-file.

```
%% point(A){5,5} (5,5)
%% point(B){10,10} (10, 10)
%% drawThickline(AB)
\setplotsymbol({\large .})
\plot 5 5 10 10 / %% AB
\setplotsymbol({\tiny .})
```

[^6]
## Recommendations

Since $\mathrm{P}_{\mathrm{I}} \mathrm{T}_{\mathrm{E}} \mathrm{X}$ uses two groups of commands for controlling the thickness of lines (i.e. \linethickness and \setplotsymbol) it is important to use pairs of equivalent commands for 'rules' (horizontal and vertical lines) and dots (all other lines) when changing line-thickness. These are shown in Table 2 for a 10 -point font (note that the default sizes are 0.4 -point and $\backslash$ tiny).

Table 2: Equivalent $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands for a 10 -point font

| rules (horizontal/vertical) | all other lines |
| :--- | :--- |
| \linethickness=1.35pt | \setplotsymbol(\{\Large .\}) |
| \linethickness=1.1pt | \setplotsymbol(\{\large .\}) |
| \linethickness=0.9pt | \setplotsymbol(\{\normalsize .\}) |
| \linethickness=0.4pt | \setplotsymbol(\{\tiny .\}) |

The author's experience is that although mathsPIC does have commands for drawing thick lines and thick arrows, it is generally better to control the line-thickness separately using the two $\mathrm{P}_{\mathrm{I}} \mathrm{CT} \mathrm{EX}$ commands shown in Table 2, and to make separate macros where necessary. For example, the following code draws a medium-thick line $A B$ by invoking the command \mediumthickline.
\newcommand\{\mediumthickline\}\{\linethickness=1.1pt\setplotsymbol(\{\large .\})\}\%

```
\mediumthickline\%
```

drawline (AB)

### 4.7 Text

Text is typeset using the text command and, by default, is centered both horizontally and vertically at a defined point. For example, the triangle symbol $\triangle$ would be placed at the point $Z$ using the command text (\$ triangle\$) \{Z\}.

Text can be located relative to a point-location using the shift ( $d x, d y$ ) or polar ( $r, \theta$ ) commands. For example, points $P_{1} P_{2} P_{3}$ could have their labels located 4 units from each point as follows.

```
variable(d){4}
text($P_1$) {P1,shift(-d,0)}
text($P_2$){P2,polar(d,10 deg)}
text($P_3$){P3,polar(d,0.29088 rad)}
```

Optionally, text can be positioned relative to a given point using appropriate combinations of the case sensitive $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ options 1 t r B b to align the left edge, right edge, top edge, Baseline, bottom edge of the text respectively, as described in the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ manual (see Section 9.5). For example in the diagram below, the text box a nice box is aligned such that the right edge of the text box is centered vertically at the point $P$ using the [r] option as follows.
point(P) $\{25,5\}$
text ( $\backslash \mathrm{fbox}\{\mathrm{a}$ nice box\}) $\{\mathrm{P}\}[\mathrm{r}]$

Text can also be placed at a point-location (using a DrawPoint command), if the text is defined as the optional point-symbol (in square brackets) associated with a point command. Although this is useful in certain circumstances, this method is somewhat less flexible than the text command, since the drawPoint command centers the point-symbol vertically and horizontally over the point-location.

## 5 Error-messages

A certain amount of syntax checking is performed by mathsPIC. Error-messages appear in the output-file (.mt file) and also in the log-file (.mlg file).

### 5.1 Output-file

A line containing an error is prefixed by $* * *$; the associated error-message appears on the next line and is prefixed by dots (...). If the /b switch is used then a beep is sounded if an error occurs during processing.

Runtime errors most commonly arise when an argument has been omitted, or division by zero has been attempted. Syntax errors are where the mathsPIC commands are written incorrectly (e.g. missing bracket). A typical example might be in a draw command if a point has not been previously defined resulting in a 'point-name' error as follows.
\%\% *** drawTriangle(T1T6T3)
$\% \%$... ?syntax error: point T6 is not defined
If the maximum point/variable allocation (default is 50) is exceeded, then a so-called 'fatal error' arises and the program terminates. In the following example, a fatal error occured while the program was trying to define a new point $Z_{3}$.
$\% \%$ *** point (Z3) $\{\mathrm{P}, \operatorname{shift}(2,5)\}$
$\% \%$... FATAL ERROR: points used exceed allocation
$\% \%$... use the PointNumber() command to increase allocation
Some other examples of error-messages are as follows.

```
%% *** point(a2{5,6}
%% ... syntax error: extra or missing ()
%%
%% *** point(B2){A,shift(,6)}
%% ... syntax error: missing X coordinate in shift()
%%
%% *** point(z2){}
%% ... runtime error: ?syntax error
%%
%% *** pointt(z4){2,3}
%% ... ?syntax error: statement not recognised
%%
%% *** drawLine(AB)
%% ... ?syntax error: points A and B are the same
%%
%% *** variable(d){j, advance(4)}
%% ... ?syntax error: j is a Point not a Variable
```

### 5.2 Log-file

mathsPIC outputs a log-file (.mlg file) which contains details of all errors, relevant line numbers and file names (e.g. <myfile.m>). The format was designed to match that of a standard $\mathrm{T}_{\mathrm{E}} \mathrm{X} \log$-file in order to be compatible with commonly used error-checking utilities. Part of a typical log-file is as follows.

```
mathsPIC log-file = myfile.mlg
mathsPIC input-file = myfile.m
mathsPIC output-file = myfile.mt
```

```
! syntax error: extra or missing () bracket
1.9 point(A{10,5}

## 6 Commands

### 6.1 MathsPIC commands

Although mathsPIC commands are not case sensitive, it is recommended (to avoid confusion) that points are represented using upper case letters, and variables are represented using lower case letters.

The parameters of mathsPIC commands are either strings (any legitimate $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ or $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ commands or characters which are suitable for an $\backslash$ hbox are allowed), point-names (e.g. A,B,C), or scalar quantities. Where appropriate, MathsPIC allows scalar quantities in commands to be represented by either a numeric value (e.g. 0.432 , or $4.32 \mathrm{E}-1$ ), a variable name (e.g. r2), or the Pythagorean distance between two points (e.g. $A B$ ). For example, the structure of a DrawCircle (center, radius) command is quite flexible, as follows.
drawCircle(C,4.32)
drawCircle(C,3.6E-1)
drawCircle(C,r2)
drawcircle(C,AB)
The various parameters which control the thickness of lines, arrows and curves drawn by $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ are described in Section 4.6.1.

- $\backslash \ldots \quad \backslash_{\llcorner } \ldots$

A line having a leading backslash is processed (copied verbatim) slightly differently depending on whether the character following the backslash is a space or not.
A leading backslash followed by a non-space character tells mathsPIC to copy the whole line verbatim (including the backslash) through to the output-file (thus a line leading with the IATEX command \begin\{document\} will be copied unchanged). }
However, a leading backslash followed by one or more spaces, (e.g. \ь...) tells mathsPIC to copy the rest of the line verbatim through to the output-file, but without the leading backslash.

- Arrowshape ( $L, B, C$ )

This command defines the shape of an arrowhead, and allows different arrowheads to be customised (see Section 7.3 for details). The default arrow shape is equivalent to the command

Arrowshape $(2,30,40)$. This default arrowhead shape can be reset using default as the argument, as shown in the following example.

Arrowshape (4,30,60)
drawArrow(AB)
ArrowShape(default)

- DrawAngleArc\{angle(), radius(), internal, clockwise\}

This command draws an arc in the specified angle, a distance radius from the angle. The angle is either internal $\left(\leq 180^{\circ}\right)$ or external $\left(\geq 180^{\circ}\right)$. The direction of the arc is either clockwise or anticlockwise, and this direction must correspond with the letter sequence specified for the angle. Strange and unexpected results will be produced if the four parameters are not internally consistent.
For example, the following command draws a clockwise arc, radius 3 units, in the external angle $A B C$, from line $A B$ to line $B C$.

DrawAngleArc\{angle(ABC), radius(3), external, clockwise\}

- DrawAngleArrow\{angle(), radius(), internal, clockwise\}

This command draws an arrow in the specified angle, a distance radius from the angle. The angle is either internal $\left(\leq 180^{\circ}\right)$ or external $\left(\geq 180^{\circ}\right)$. The direction of the arrow is either clockwise or anticlockwise, and this direction must correspond with the letter sequence specified for the angle. Strange and unexpected results will be produced if the four parameters are not internally consistent. The arrow shape for the angleArrow is currently fixed, and cannot be changed using the ArrowShape command for straight arrows (the author is happy to make this more flexible if necessary).
For example, the following command draws a clockwise arrow, radius 3 units, in the internal angle $A B C$ from line $A B$ to line $B C$.
drawAngleArrow\{angle(ABC), radius(3), internal, clockwise\}

- drawArrow $(A B) \quad$ drawArrow $(A B)[d]$ drawThickarrow $(A B, C D, F G, \ldots$ )

These commands draw arrows (or thick arrows) joining two points. The direction of the arrow is in the point order specified. The shape of the arrowhead is controlled by the ArrowShape command (see Section 7.3). Parameters which control line-thickness are described in Section 4.6.1

```
drawArrow(AB)
drawArrow(FG, HJ)
drawThickarrow(BC)
drawThickarrow(PQ, RS)
```

An arrow can also be drawn a specified distance from one point towards another point, using a square-bracket option. For example, the following command draws an arrow a distance $d$ units from point $A$ towards point $B$.

```
drawArrow(AB) [d]
```

- DrawCircle(center, radius)

This command draws a circle defined by its radius and the point-name of its centre. The radius argument can be either a decimal, a variable, or the Pythagorean length of a line (e.g. AB). The following example draws a circle centre $C_{2}$, and radius 5 units.

```
drawCircle(C2,5)
```

In the following example, the radius argument is the variable r2.

```
drawCircle(C2,r2)
```

In the following example, the radius argument is the Pythagorean length of the line $A B$.

```
drawCircle(C2,AB)
```

Note that $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ draws circles with the \circulararc command, using a radius equivalent to the distance from the center to the point at which it starts drawing the arc. Consequently, if the units of the $x$ and $y$ axes are different, circles may be drawn strangely. MathsPIC therefore generates a message to this effect in the output-file if different units are selected for the two axes in the units command (see Section 4.3.2).

- DrawCircumcircle ( $A B C$ )

This command draws the circumcircle of the triangle defined by the points A, B, C.

- DrawCurve (ABC)

This command draws a smooth quadratic curve through three points $A, B, C$ in the point order specified. At present it uses the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X} \backslash \mathrm{plot}$ command, and so it is only recommended for three points (for more than three points the resulting curve is unlikely to be 'smooth'). This command will be upgraded in the next version to give a smooth curve for more than three points.
Note that curves drawn using this command do not break to avoid line-free zones associated with the points (the drawLine command for straight lines does acknowledge line-free zones).

- DrawExcircle $(A B C, A B)[\delta r]$

This command draws the excircle touching side $A B$ of the triangle $A B C$. The optional argument [ $\delta r]$ is a fine adjustment to the radius of the excircle circle to facilitate drawing the figure in certain circumstances.
In the following two examples, the first draws the true excircle, while the second draws the excircle with its radius reduced by 0.2 units.

```
drawExcircle(T1T2T3, T1T2)
```

drawExcircle(T1T2T3, T1T2) [-0.2]

- DrawIncircle $(A B C)[\delta r]$

This command draws the incircle of a triangle. The optional argument $[\delta r]$ is a fine adjustment to the radius of the incircle circle to facilitate drawing the figure.

In the following two examples, the first draws the true incircle, while the second draws the incircle with its radius reduced by 0.2 units.

```
drawIncircle(T1T2T3)
```

drawIncircle(T1T2T3) [-0.2]

- drawline (ABCD...) drawline (AB)[6] drawline (AB, CD, EFG, ...)

## drawline*(ABCD...)

This command draws a line joining two or more points. Lines are drawn in the order specified. Lines are not drawn within line-free zones of points.
Parameters which control line-thickness are described in Section 4.6.1.

```
drawline(AB)
drawline(BCDE)
drawline(FG, HJK, PQRST)
```

A line can also be drawn a specified distance from one point towards another point, using a square-bracket option. For example, the following command draws a line a distance $d$ units from point $A$ towards point $B$.

```
drawline(AB) [d]
```

Note that some restrictions are associated with the square bracket option: (a) it can only be used when drawing a single line; (b) a line-free zone associated with the second point will be ignored, (c) the order of the points $A B$ is important-the line is drawn from the first point towards the second point (see Figure 11).
Note that the drawline command uses the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \putrule command for horizontal and vertical
 disabled when using the mathsPIC drawline* command, which uses only the \plot command for all lines. Since the $\backslash$ plot command should be used when using larger than normal dots ( $\backslash$ setdots) for horizontal or vertical lines, then this is achieved with the drawline* command.

- DrawPerpendicular (point, line) [foot]

This command draws the perpendicular from point to the line. If the option [foot] is specified, then this command also draws the current pointsymbol() character (default point-symbol is $\$ \backslash$ bullet $\$$ ) at the point where the perpendicular joins the line. The following example draws the perpendicular from the point $P$ to the line $A B$.
drawPerpendicular ( $\mathrm{P}, \mathrm{AB}$ )

- drawpoint (name) drawpoint (name1 name2 ... )

This command draws the point-symbol at the point-location. Commas must not be used to separate points. The default point-symbol is $\$ \backslash$ bullet $\$$, unless an optional point-symbol (or string of characters) was specified in the associated point command. If the [circle] option was used with the point command without a radius parameter, then the $\$ \backslash$ circ $\$$ symbol will be used (see the point command).
drawpoint(T4)
drawpoint(ABCDEF)
drawpoint(P1 P2 P3 P4)

- DrawRightangle(angle, symbolsize)

This command draws the standard right-angle symbol in the internal angle specified. The following example draws a right-angle symbol (side 3 units) in the internal angle ABC.

```
drawRightangle(ABC,3)
```

- drawThickline (ABCD...) drawThickline (AB)[d] drawThickline( $A B, C D, E F G, \ldots$ )

This command draws a thick line joining two or more points in the point-order specified. Lines are not draw within line-free zones associated with points.
Parameters which control line-thickness are described in Section 4.6.1.

```
drawThickline(AB)
drawThickline(BCDE)
drawThickline(FG, HIJ)
```

An arrow can also be drawn a specified distance from one point towards another point, using a square-bracket option. For example, the following command draws an arrow a distance $d$ units from point $A$ towards point $B$.
drawThickArrow(AB) [d]

- DrawTriangle $(A B C)$

This command draws the triangle defined by the points $A, B, C$. Note that drawTriangle (ABC) is equivalent to drawLine (ABCA). The drawTriangle command checks that the area is not zero, and generates an error-message if it is (note that this area check is not made when using the equivalent drawLine (ABCA) command to draw a triangle).

- inputFile(mathspic.doc) [loop] inputFile*(pictex.doc)

The inputFile command inputs a plain text file containing mathsPIC commands. Optionally, the file can be input [loop] times, in which case this command functions like a DO-LOOP. For example, the following command inputs the file newfile.dat 4 times in succession.
inputFile(newfile.dat) [4]

The inputfile* command is used to input a file in verbatim, i.e. a file with no mathsPIC commands. For example, a file containing only $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands or data-points for plotting etc. A typical example might be the following file (curve-A.dat) which would be input verbatim using the command inputfile*(curve-A.dat).

```
%% curve-A.dat
\setquadratic
\plot 0 0
        3.56 4.87
        8.45 9.45
        5 7
        2.34 3.23 /
\setlinear
```

Note that the inputfile* command has no [loop] option.

- paper\{units( ),xrange( ),yrange( ),axes( ),ticks( )\}
units(unit) or units(xunit,yunit)
xrange (xlow,xhigh)
yrange (ylow,yhigh)
axes ( $X Y L R T B$ )
ticks $(x, y)$
The paper\{. . \} command defines a plot area with optional axes and tick-marks (see Section 4.3.1).
For example, the following statement sets up a rectangular drawing area $50 \mathrm{~mm} \times 50 \mathrm{~mm}$ with axes on the Left (y-axis) and Bottom (x-axis), and tick marks at 10 mm intervals.
paper\{units $(\mathrm{mm})$, xrange $(0,50)$, yrange $(0,50)$, axes $(\operatorname{LB})$, $\operatorname{ticks}(10,10)\}$

All combinations of the axis-codes (XYLRTB) are allowed, and a following an axis-code (e.g. $\left.L^{*}\right)$ stops ticks being drawn on the specified axis.

If it is necessary to have different unit scales for the $x$ and $y$ axes, say 1 cm and 2 mm respectively, then this is implemented by units $(1 \mathrm{~cm}, 2 \mathrm{~mm})$, or units $(\mathrm{cm}, 2 \mathrm{~mm})$. If there is no digit associated with a unit (e.g. mm ), then mathsPIC actions the command as 1 mm . If only a single unit is specified (e.g. units (cm)) then mathsPIC automatically makes this the unit scale for both axes. If the unit option is omitted $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ will use the last defined units (within the same picture environment), the default units being xunit=1pt and yunit=1pt (see the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ Manual, page 3; Wichura, 1992).
point(name) $\{. .$.$\} [symbol, linefree radius]$
point*(name)\{...\}[symbol, linefree radius]
The point command is used to define points. Note that a point-name must begin with a single letter (either upper or lower case), and may have up to a maximum of two following digits.
The default point-symbol is the $\$ \backslash$ bullet $\$$. An optional alternative point-symbol (or string of characters) can be specified within square brackets e.g. [\$\triangle\$] (see Section 4.4).
By default lines are drawn to the point location. However, the radius of an optional line-free zone can be specified within an optional square bracket e.g. [\$\triangle\$,4] (see Section 4.4). If a line-free radius is specified without a point-symbol, then the preceding comma must still be included; for example [,5].
An optional 'circle' can also be used as the symbol. If a radius value is also included, e.g. [circle, 5] then a circle will be drawn having the specified radius (the radius value will also be assumed to be the line-free radius). If no radius value is specified, e.g. [circle], then the small circle symbol ( $\$ \backslash \operatorname{circ} \$$ ) is used instead (and line-free radius set to zero).
Points can also be defined relative to previously defined points. For example, as the intersection of two existing lines, or as a + ve or -ve extension (in the direction indicated by the letters) between two previously defined points, etc.
The point* command re-allocates new parameters (e.g. coordinates, point-symbol, or line-free radius) to a previously defined point-name.
Some examples of valid point commands are as follows.

```
point(A){5,5}
point(B2) {22,46}[circle]
point(B2) {22,46}[circle,5]
point(C32){3,8}[$\Box$]
point(D1){20,2}[$\Box$,4]
point(D10){20,5}[,4]
point(D2) {B2, shift(5,5)}
point(D3){D2, polar(6,32 deg)}
point(D4){D2, polar(6,1.2 rad)}
point(D2){intersection(AB,CD)}
point(F){PointOnLine(AB,5.3)}
point(G){perpendicular (P,AB)}
point(G2){Q, rotate(P, 23 deg)}
point(H){circumcircleCenter(ABC)}
point(J){incircleCenter(ABC)}
point(K){excircleCenter(ABC,BC)}
point*(A) {6,3}
point*(B) {B, shift (5,0)}
point*(C) {C}[,6]
```

- PointNumber(n)

This command allows the array space used for holding the total number of points and variables (combined) to be increased (or decreased). This statement must therefore be placed before any point statements, and so is best used right at the beginning of the mathsPIC file. The default number is set at 50 points.

PointNumber (55)
If the total number of points and variables combined exceeds the allocated number then a 'fatal error' is triggered, and the program terminates (see Section 4.4.5).

- PointSymbol(symbol, linefree radius)

This command allows the default point-symbol (\$ $\$$ bullet\$, line-free radius zero) to be changed. The syntax of this command mirrors exactly that of the square-bracket option associated with the point command. The PointSymbol command is particularly useful where a set of points uses the same point-symbol (Figure 16), and also when drawing graphs (Figure 15).
For example, the following command changes the point-symbol to $\odot(\$ \backslash \operatorname{odot} \$)$ having a line-free radius of 0.7 units.

```
PointSymbol($\odot$, 0.7)
```

Note that the PointSymbol command only influences subsequent point commands. For example, the following commands will make points $A$ and $B$ be drawn as circles having radius of 5 units.

```
variable(r){5}
PointSymbol(circle,r)
point(A){5,5}
point(B){10,12}
```

Note that the optional square bracket of the point command overrides the PointSymbol command. The point-symbol can be reset to the default • (\$ bullet\$) using the command PointSymbol (default).

- show ...

This command forces mathsPIC to return the value of a calculation or specified parameter; for example, the value of a particular angle, or the length of a line. The result is shown in the output-file as a commented line. This allows mathsPIC commands to be adjusted in the light of calculations.

```
show(B) %% for both Points and Variables
show(r) %% for both Points and Variables
showLength(AB)
showIntersection(AB,CD)
showAngle(ABC)
showArea(ABC)
```

When the above examples are processed, the results appear as commented lines in the output-file as follows.

```
%% show(B) Point (22.12432, 18.96723)
%% show(r) Variable (8.25367)
%% showLength(AB) 25.35746
%% showIntersection(AB,CD) (15.13245, 22.74723)
%% showAngle(ABC) 39.35746 degrees (0.68691 radians)
%% showArea(ABC) 54.54267
```

- text (string) $\{x, y\}$ [position]
text (string) \{pointname, adjustment $\}$ [position]
where the adjustment option is either $\operatorname{shift}(d x, d y)$ or $\operatorname{polar}(r, \theta)$.
This command puts the given text-string either at the named point, or with a displacement specified by the optional shift ( $d x, d y$ ) or polar $(r, \theta)$ parameters. By default the text is centered vertically and horizontally at the specified point.
Optionally, text can be placed relative to a point using appropriate combinations of the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ position options 1 t r B b to align the left edge, right edge, top edge, Baseline, bottom edge respectively of the text box with the point-location (see the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ Manual, page 5; Wichura, 1992). For example, the text box This is point $P$ would be aligned such that the right edge of the text box would be centered vertically at the point $P$, using text (This is point $P$ ) $\{P\}[r]$.
The text command can be used to label points, or to simply position text in a diagram, as shown in the following examples.

```
text(A){5,6}
text($A_1$){A1, shift(2, 2)}
text($Z2$){Z2, shift(5, -5)}[tr]
text($Z3$){Z2, polar(5, 20 deg)}[Br]
text($Z4$){Z2, polar(5, 1.34 rad)}
text(\framebox{$Z5$}){Z3}
```

- variable (name) \{value\}
variable*(name) \{value\}
The variable command is used to define scalar variables (see Section 4.5). Note that a variablename must begin with a single letter (either upper or lower case), and may have up to a maximum of two following digits. Variables and points have the same name structure, and a variable cannot have the same name as a point. The scalar argument in the braces can be either a numeric value, another variable, or two points (implying the distance between the two points).

New values can be re-allocated to existing variable-names using the equivalent variable* command; thus the variable r3 can be re-allocated the value 15 using the command variable* (r3) \{15\} (if the variable-name has not been used before then mathsPIC will generate an error message).

Variables can be manipulated using the commands advance, multiply, divide and mod.
The following are examples of valid variable commands.

```
variable(r3){20}
variable(z3){3.46E-2}
variable(r4){r1}
variable(r5){AB}
variable*(r5){6}
variable(x1){w, advance(-6)}
variable(x2){w2, divide(-p)}
variable(x3){AB, multiply(2)}
variable*(x1){x1, mod(3)}
variable(g){angle(ABC)}
variable(g2){area(ABC)}
variable(x3){Xpoint(P3)} % gets the x-coordinate of a point
variable(y3){Ypoint(P3)} % gets the y-coordinate of a point
variable(p1){3.14159} % use p1 to represent Pi
variable(e){2.71828}
```

### 6.2 Summary of mathsPIC commands

The following list shows the format and typical usage of all mathsPIC commands. Although mathsPIC commands are not case sensitive, in this summary of commands points are represented using upper case letters, and variables are represented using lower case letters. Note that a leading $\backslash_{\nu}$ is used for copying $\mathrm{T}_{\mathrm{E}}$ or $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ lines verbatim, for example with macros or coordinates of data points etc.

```
\4.5 6.3

variable(e){2.71828}
variable*(r1) {20}
variable*(x1){x1, mod(3)}
```

Note that the old latex\{...\} pictex\{...\} and tex\{...\}'wrapper' commands (for copying their argument unchanged into the output file) have been superseded by the more convenient $\backslash$ and $\backslash_{\llcorner }$ commands, but are still available to allow downwards compatibility with earlier versions of mathsPIC.

### 6.3 Useful $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands

The following is a list of $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands which are particularly useful for including in the mathsPIC file, mainly for controlling the thickness of lines and axes, customising dash patterns and symbol spacing, and for plotting and rotation. Note that there is a section on $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ in Alan Hoenig's recent book $T_{E} X$ Unbound ${ }^{9}$ which also includes a brief list of commands. Note that where small angle brackets are shown (e.g. <) then these must be used exactly as shown.

```
\grid {cols} {rows} %% eg \grid {5} {10}
\setdashpattern <4pt, 2pt>
\setdashes <7pt> %% equivalent to \setdashpattern <7pt, 7pt>
\setdashes %% default is \setdashes <5pt>
\setdots <4pt>
\setdots %% default is \setdots <5pt>
\setsolid %% sets solid-line mode (ie not dashes/dots)
\setlinear %% sets straight-line plotting mode (ie not quadratic)
\setquadratic %% sets curved plotting for graphs etc
\setplotsymbol({\large .})
\setplotsymbol({\tiny .}) %% default size for curves (used by \plot)
\plotsymbolspacing=2pt %% sets spacing between plot symbols (used by \plot)
\plotheading{..} %% eg \plotheading{This is a quadratic curve}
\headingtoplotskip=1cm %% separation between plotheading and graph
\linethickness=2pt %% for horiz & vert lines: default 0.4pt
\frame <sep> {text} %% eg \frame <5pt> Hello
\rectangle <width> <height> %% eg \rectangle <2cm> <1cm>
\putrectangle corners at 5 10 30 5 %% corners at Top-left Bottom-right
\inboundscheckon %% restricts plotting to plotting area
\inboundscheckoff %%
\normalgraphs %% restores default values for graph parameters
\circulararc 30 degrees from 3.5 4.5 center at 5 5
\ellipticalarc axes ratio 2:1 360 degrees from 3 3 center at 5 5
(axes ratio is major-axis:minor-axis, ie a:b)
```

Note that $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ also has an excellent rotation facility. $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ will rotate about a given point, by a given angle, all picture elements (but not text) which are detailed between its \startrotation... and \stoprotation commands. However the decimal value of the Sine and Cosine angle must be supplied (see below). If the point is not specified then rotation is performed about the origin. The format is as follows.
\startrotation by $\cos (t) \sin (t)$ [about $x y]$
...
\stoprotation
This command is particularly useful for rotating curves. For example, to rotate an ellipse by 30 degrees about the point $(5,5)$ one would write
\startrotation by 0.866020 .5 about 55
\ellipticalarc.....
\stoprotation
A $\mathrm{P}_{\mathrm{I}} \mathrm{CTE}_{\mathrm{E}} \mathrm{X}$ error-bar facility is also available by loading the file errorbar.tex (see Section 9.4). Note that $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ does allow more sophisticated graph axes and tick-marks to be setup, as well as shading of enclosed areas. However, these are complicated and require access to the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{EX}}$ Manual (see Section 9.5), and are currently outside the scope of mathsPIC.

[^7]
## 7 Examples

This section describes some practical examples of figures drawn using mathsPIC, together with the associated code. A collection of more complicated examples can be found in the the companion document examples.tex which is included in the mathsPIC package.

When drawing a new figure or diagram, the author finds it best to start with a graduated coordinate frame (see Figure 1) using the axes and ticks options of the paper command. The next step is to define an anchor point from which other points can be derived - this has the advantage that the whole figure can then be moved by simply changing the coordinates of the anchor point. If necessary, different parts of a complicated figure can be made having their own separate anchor points, allowing the various parts to be easily adjusted relative to each other. Finally (if the frame is not required), the frame should be moved close to the edge of the figure by adjusting the xrange and yrange parameters, in order to remove unnecessary surrounding white space, after which the the axes and ticks options of the paper command can be removed, ready for inserting into the document. The code can then be either pasted into the document directly, or kept as a separate file and then \input as required.

As regards scales and units, the author finds it most convenient to use the mm units and to keep the $x$ and $y$ scales the same whenever possible (i.e. use paper\{units ( mm ) $\ldots$. \}), since this allows easy scaling up and down after the figure has been finished (see Section 4.3.2 for details regarding the use of variables to control the units).

The appropriate $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ commands to \input the file and position the graphic on the page are described in Section 8.

### 7.1 Input- and output-files

The following example mathsPIC file (input-file) illustrates how some of these commands are used to draw Figure 4. Note that the dashed line $A D$ is drawn after the $\mathrm{P}_{\mathrm{T}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \setdashes command is invoked; following this \setsolid is used before drawing the right-angle symbol. Also, the points $A, B, C$ are defined using the $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ lodot symbol $\odot$, in conjunction with a line-free zone of 1.2 mm in order to make the lines go to the edge of the symbol - the value of the radius of such $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ symbols has to be determined by trial and error-see Table 1 (Section 4.4.3).

Figure 4:

showLength(AC)
showArea(ABC)
\endpicture
%------------------
\end{document}
```

When the above file is processed by mathsPIC the output-file (.mt file) is as follows. Note how the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands are preceded by their mathsPIC commands (commented out), some of which have additional information added (e.g. the coordinates of a derived point-see the line \%\% point (D)... ). Being able to compare the mathsPIC and resulting $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands in the output-file is particularly useful when debugging. Note also how the show commands return the lengths $\mathrm{AD}, \mathrm{BC}$, and the area ABC.

```
% mPICm04.m (Figure 4)
```

\endpicture
\%----------

Note that the remaining comments at the end of the \plot and \put lines are generally sufficient to understand what each line relates to. Note also that the CLEAN.EXE utility only removes lines having a leading \% \% pair of characters, so comment lines prefixed with only a single \% character will remain.

### 7.2 Line modes

When drawing figures with both solid and dashed lines it is necessary to switch between the $\mathrm{P}_{\mathrm{T}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands \setdashes and \setsolid (see Section 6.3), as in the following code for drawing the rectangular box shown in Figure 5.

The default \setdashes gives alternating lines and spaces, each of width 5pt. More fancy dashpatterns (see Figure 5) can be easily generated using the $\mathrm{P}_{\mathrm{I}} \mathrm{CT} \mathrm{EX}$ \setdashpattern command which defines the pattern cycle, and hence takes an even number of parameters. If a particular dash-pattern is to be used several times in a figure, then a defining macro may be useful, as follows.
\def $\backslash \mathrm{fancydashes}\{\backslash$ setdashpattern $<6 \mathrm{pt}, 2 \mathrm{pt}, 1 \mathrm{pt}, 2 \mathrm{pt}>\}$
$\backslash f a n c y d a s h e s$
Note that in Figure 5 all the points are defined, directly or indirectly, relative to point $A$, with the effect that the position of the whole figure can be adjusted simply by altering the coordinates of point $A$. This can be useful when drawing diagrams having several components since the relative position of each component can then be easily adjusted.

Figure 5:

```
%% mPICm05.m (Figure 5)
\beginpicture
paper{units(mm), xrange(0,50), yrange(0,62)}
variable(s){20} % Sides front & back
variable(L){34} % Length
variable(a2){56.6} % Angle degrees

text($F$){F, shift(2,4)}
text($G$){G, shift(-1,4)}
text($H$){H, shift(-4,1)}
\endpicture
```

### 7.3 Arrows

Arrows can be drawn in all possible orientations, will stretch between points, and arrow-heads are readily customised using the mathsPIC Arrowshape command (see also Salomon, 1992).

Although arrow shape can of course be controlled using standard $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands, the mathsPIC Arrowshape command makes this easier by allowing you to define the angle parameters ( $B$ and $C$ ) of the arrow-head directly (see box). The default arrowshape is equivalent to the following command

Arrowshape (2,30,40)

Figure 6:

If the arrowshape has been altered, it can be reset using the command ArrowShape (default). Curved arrows (circular arcs) are drawn using the drawAngleArrow command, which takes parameters for the angle, radius of arc, direction, and whether the angle is internal or external (see Figures 7 and 8).

Arrows can also be used to link elements in a diagram, as shown in Figure 8. The right-hand diagram uses the drawArrow command; the small gap between the arrows and the letters $P, Q, R, T$

```
% mPICm07.m (Figure 7)
\beginpicture
paper{units(mm),xrange(5,45),yrange(5,45)}
point(A){30,30}
point(P){10,10}
point(B) {30,10}
drawPoint(APB)
drawLine(APBA)
text($A$){A,shift (1,5)}
text($B$){B,\operatorname{shift}(5,0)}
```

Figure 7:

```
text($P$){P,shift(-5,0)}
drawAngleArrow{angle(BPA),radius(11),anticlockwise,internal}
text($\psi$){P,polar(7,22.5 deg)}
drawRightangle(ABP,2.5)
\endpicture
```

being due to the 5 unit line-free radius associated with these points (see mpicm08b.m). The arrows are easily 'stretched' to accommodate their labels simply by adjusting the separation of the nodes using the polar $(r, \theta)$ commands (cf. Feruglio, 1994).

Figure 8:

```
%% mpicm08a.m (Figure 8a)

text($p_3$){P3,shift (2,-2)}
point(T1){midpoint(TR)}
text($t$){T1,shift(3,0)}
point(Q1){midpoint(QR)}
%% use a macro for the label
\newcommand{\q}{$q\star q \star q \star q \star q$}
text(\q) {Q1,shift (-1,3)}
\endpicture
```

### 7.4 Circles

MathsPIC allows the point-symbol to be designated as a circle using the [circle,r] option to the point command, which not only gives the circles an internal line-free zone, but also arranges that they are drawn by the drawPoint command, as shown in Figure 9. This construction greatly simplifies the drawing of directed graphs, trees and equivalent structures.

Figure 9:

```
%% mPICm09.m (Figure 9)
\beginpicture
paper{units(mm),xrange(0,70),yrange(0,60)}
point(A){30,11}[circle,8]
point(B){A,shift(-10,30)}[circle,15] %% big circle
point(C){A,polar(30,20 deg)}[circle,5]
point(D){A,polar(45,50 deg)}[circle,7]
drawPoint(ABCD)
drawLine(AB , AC, BC, BD ,CD)
\setdashes
drawLine(AD)
text($A$){A}
%% use a macro for the formula
\newcommand{\formula}{%
\ $\displaystyle \sum_{p\ge0} \Delta_{jp} z^{(p+1)}$%
\ }%
text(\formula) {B}
text($C$){C}
text($D$){D}
\endpicture
```

Note that in this particular case it is necessary to define the maths formula using \displaystyle, in order to avoid the embedded \textwidth white space associated with using \vbox\{\formula\} in the $\backslash$ text () command, and hence allow centering of the figure. Note also how the mathsPIC $\backslash_{\llcorner } .$. commands make it easy to include multi-line macros in the mathsPIC file.

Points on circles (and their labels) are most easily defined and positioned using the polar $(r, \theta)$ option, as shown in the mathsPIC file for Figure 10. Notice the use of the variable $r$ for the radius of the circle (allocated using the command variable(r)\{20\}), which then allows the use of $r$ to define the radius in the polar commands for the points $P, Q, S$.

Figure 10:

```
%% mPICm10.m (Figure 10)
\beginpicture
paper{units(mm), xrange(5,55), yrange(5,55)}
point(C) {30,30}[$\odot$,1.2] %% center
variable(r){20} %% radius
drawcircle(C,r)
point(P){C, polar(r,250 deg)}
point(Q){C, polar(r,120 deg)}
```

```
point(S){C, polar(r,-30 deg)}
drawpoint(CPQS)
drawline(PCSQP)
text($P$){P, polar(5,250 deg)}
text($Q$){Q, polar(5,120 deg)}
text($S$){S, polar(5,-30 deg)}
drawAngleArrow{angle(PCS), radius(8) anticlockwise internal}
text($\beta$){C, polar(5,285 deg)}
drawAngleArrow{angle(PQS), radius(12) anticlockwise internal}
text($\alpha$){Q, polar(8,-65 deg)}
show angle(PQS) % alpha
show angle(PCS) % beta
\endpicture
```

Note that the returned values in the output-file from the showAngle commands (see below) for Figure 10 indicate that $\beta$ is twice $\alpha$, as one would expect.
\%\% showAngle(PQS) 40 degrees / radians 0.6981316 \% alpha
$\%$ showAngle(PCS) 79.99999 degrees / radians $1.396263 \%$ beta
MathsPIC offers a range of other circle commands (drawIncircle, drawExcircle, drawCircumcircle), specifically for geometry diagrams (cf. Cameron, 1992), as shown in Figure 11.

Figure 11:
\%\% mpicm11.m (Figure 11)

```

### 7.5 Functionally connected diagrams

When constructing diagrams it is often useful to write the mathsPIC file in such a way that the position of each new point is related to that of earlier points, since then the structure of the diagram is maintained even when points are moved. This is demonstrated in Figure 12, where the mathsPIC code for the two diagrams differs only in the angle of the line $A B$ (left diagram, 60 degrees; right diagram, 5 degrees) as defined in the point (B) $\{\ldots\}$ command as follows.

- Left-hand diagram: point(B) \{A, polar (45,60 deg) \}
- Right-hand diagram: point (B) $\{\mathrm{A}, \operatorname{polar}(45,5 \mathrm{deg})\}$

Figure 12: The mathsPIC code for the two diagrams differs only in the angle of the line $A B$ as defined in the point (B) $\{\ldots\}$ command (see mPICm12.m).

```
%% mPICm12.m (Figure 12)
\beginpicture
paper{units(mm),xrange(5,120),yrange(0,45)}
point(A){15,5}[$\odots$,1.2]
point(P){A,shift (10,30)}[$\odots$,1.2]
point(B){A,polar(45,60 deg)}
point(Q){perpendicular(P,AB)} % from P to line AB
drawRightangle(PQA,2)
drawPoint(ABPQ)
drawLine(ABPQ)
drawIncircle(PQB)
text($A$){A,shift(-5, 0)}
text($B$){B,shift(5, 0)}
text($P$){P,shift(-5, 0)}
point(S) {pointOnLine(QP,-5)}
text($Q$){S}
%% now draw vertical line and angle
point(N){A,shift(0,12)}
\setdashes
drawLine(AN)
\setsolid
drawAngleArrow{angle(NAB),radius(7),clockwise,internal}
\endpicture
```

Note that in Figure 12 the location of the label 'Q' is made to lie outside the figure by placing the label at point $S$, which is defined as being 5 mm to the right of line AB in-line with the points PQ , using the command point (S) \{pointOnLine (QP, -5) \}.

### 7.6 Inputting files and recursion

mathsPIC allows the recursive input of blocks of mathsPIC commands as files, using the inputfile command. In practice, this functions as a 'DO-LOOP' in a program. For example, the file myfile.dat would be input six times sequentially using the command inputfile(myfile.dat) [6].

Figure 13:

Figure 13 was produced by the following code which inputs a small file of mathsPIC code (mpicm13.dat) recursively 30 times using the command inputfile (mpicm13. dat) [30]. Note the use of the variable* and point* commands and the advance operator in order to re-allocate variables and points recursively.

```
%% mpicm13.m (Figure 13)
%% spiral
\beginpicture

point*(Q3){P,polar(s,180)}
point*(Q4){P,polar(s,270)}
drawline(Q1Q2Q3Q4Q1)
```

### 7.6.1 Plotting graphs

Data-files which do not contain mathsPIC commands can be input using the inputfile* command. This command inputs files verbatim, and so can be used for inputting files containing, for example,
only $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands and/or points for plotting curves (see Section 6). For example, the following mathsPIC code (mpicm14.m) draws the quartic curve shown in Figure 14, by inputting in verbatim a datafile (mpicm14.dat) containing some $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands and a set of data points for plotting. Note that in this example the $x$-axis is stretched by using units $(3 \mathrm{~cm}, \mathrm{~cm})$ in the paper\{\} command.

## A quartic equation

Figure 14:

```
%% mpicm14.m (Figure 14)
\beginpicture
\linethickness=1pt %% use a thick line for the axes
paper{units(3cm,cm), xrange(-1,2),yrange(-2,4), axes(XY),ticks(1,1)}
\linethickness=0.4pt %% reset to default value
\headingtoplotskip=8mm
\plotheading{\fbox{\Large A quartic equation}}
inputfile*(mpicm14.dat) %% input file containing data points for curve
variable(r){0.3} %% define a line-free radius r = 0.3
point(E1){1,3.5}[,r]
text($f(x)=6x^4-8x^3 + 1$){E1} % center the equation at E1
point(E2){1.4,2}[,r]
drawArrow(E1E2)
point(J1){0.55,2}[,r]
text(inflection points){J1} %% center inflection text at J1
point(J2){0,1}[,r]
point(J3){0.6,0}[,r]
drawArrow(J1J2,J1J3)
\endpicture
```

The datafile for the curve is as follows. Note that $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ requires an odd number of pairs of data points to satisfy its curve-drawing algorithm. ${ }^{10}$

```
%% mpicm14.dat (Figure 14)
%% quartic curve data (use an odd number of data points)
```

[^8]| \setquadratic <br> \plot |  |
| :--- | ---: |
| -0.6 | 3.50 |
| -0.5 | 2.37 |
| -0.4 | 1.66 |
| -0.35 | 1.43 |
| $\ldots$ |  |
| $\ldots$ |  |
| 1.15 | -0.67 |
| 1.25 | 0.02 |
| 1.35 | 1.24 |
| 1.45 | 3.13 |

However, when there are only a few data points, it is somtimes more convenient just to plot the points separately and then draw connecting lines, as shown in Figure 15.

Weight change with diet

Figure 15:

```
%% mpicm15.m (Figure 15)
\beginpicture
paper{units(cm),xrange(0,6),yrange(73,77), axes(LBT*R*),ticks(1,1)}

drawline(d1d2d3d4d5)
%
pointsymbol($\boxdot$,r)
point(k1){1, 75.2}
point(k2){2, 75.4}
```

```
point(k3){3, 74.8}
point(k4){4, 74.1}
point(k5){5, 74.0}
drawpoint(k1k2k3k4k5)
\setdashpattern <2pt, 2pt>
drawline(k1k2k3k4k5)
%
\plotheading{\textsf{\Large Weight change with diet}}
text(\shortstack{\textsf{\large Weight}\\($kg$)}){-1.5,75.3}
text(\textsf{\large Days}){3,72}
\endpicture
```

The drawcurve command can also be used for drawing smooth curves linking a number of points or touching lines. For example, Figure 16 shows a smooth curve touching a piecewise linear closed line ${ }^{11}$, some of the points being constructed using a Bezier technique ${ }^{12}$. The smooth curve is drawn using the drawcurve command for successive three-point sequences.

Figure 16: A smooth curve inscribed in the intersecting closed line $A B C D E F G A$

Text($F_2$){F2,shift(.05,-.2)}
Text($G_2$){G2,shift(0,.25)}
\endpicture
```

Note the technique used in the code for Figure 16, for making the physical line-free radius (r) invariant with respect to the scaling value (u) (i.e. does not change when the figure is enlarged or reduced by varying the value of the variable $u$ ), as follows (see also Section 4.3.2).

```
variable(u){12} %% units = 12 mm
paper{units(u mm),xRange(0,9),yRange(-1,6)}
variable(r){0.7} %% line-free radius of \circ = 0.7mm
variable*(r){r, divide(u)} %% scaled linefree radius for u mm
pointsymbol($\circ$, r)
point(A){1,1}
```

This technique can be very useful if it will be necessary to scale the figure markedly after having designed the figure, in order, say, to make it fit into a particular space in a document.

## 8 Positioning figures in a document

Once a diagram or figure has been finished it can be easily placed in a document either by including the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ code directly in the main document within the \begin\{figure\}... } \backslash end \{ figure \} environment, or by \inputting the code as a separate file. For example, if the mathsPIC file was called myPIC.m and this generated the output-file myPIC.mt, then one would comment-out the $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ headers and footers from the .mt file, keeping just the part of the file within the \beginpicture... \endpicture environment (renaming it, say, myPIC.pic) as follows.
\%\% this is file myPIC.pic
$\backslash$ beginpicture
...
..
\endpicture
The myPIC.pic file can then be \input into a document as a centered Figure as follows.

```
\begin{figure} [hbt]
\begin{center}
    \strut\input{myPIC.pic}
    \caption{...}
    \label{...}
\end{center}
\end{figure}
```

It is often useful when adjusting its position on the page, to initially place the Figure inside a frame in order to see the exact extent of the Figure, in which case replace the \input line above with the following:

```
\strut\framebox{\input{myPIC.pic}}
```

Sometimes more flexibility is needed regarding positioning the \caption, in which case a $\backslash$ parbox is useful, as follows:

```
\begin{figure}[hbt]
\begin{center}
    \strut\input{myPIC.pic}
    \parbox{10cm}{
            \vspace{5mm}
            \caption{...}
            \label{...}
            }
\end{center}
\end{figure}
```

When typesetting text and a figure side-by-side the following format for using two adjacent minipages works well-this was the construction used for displaying the program code and the associated Figure 7.

```
\begin{figure}[hbt]
\noindent
\begin{minipage}{4cm}
%% put some text or a figure here
...
\end{minipage}
%%-----------
\hspace{3cm} %% controls the horizontal space between Figures
%%
\begin{minipage}{4cm}
    \vspace{3mm}
    \strut\hspace*{...}\input{circle.pic}
    \vspace{...} % adjusts vertical position of caption
    \caption{...}
    \label{...}
\end{minipage}
%-----
\hfill
\end{figure}
```

Finally, it is often necessary to have two figures side-by-side, each with separate sub-captions, in which case the following rather similar format is useful-this was the construction used for displaying the two figures of Figure 8. Note the commented-out \framebox\{\} commands; these are very useful for revealing the full extent of any white-space surrounding the separate figures, since such unwanted white-space is probably the most common cause of difficulty when trying to position and center figures in a document.

```
\begin{figure} [hbt]
\begin{center}
    %-------
    \noindent %\framebox{
    \begin{minipage}{3cm}
        \begin{center}
        %\vspace{...} %% controls space above picture
        \input{mPICm08a.pic}
        %\vspace{...} %% controls space between pict and caption
        a. Circular arrows
        \end{center}
    \end{minipage}
    %} %end of framebox
```

```
%-----------------------
\hspace{12mm} %% controls horiz space between figs
% \bigskip\bigskip %% use this to place figs vertically
%----------------------
%\framebox{
\begin{minipage}{5cm}
        \begin{center}
        %\vspace{...} %% controls space between pict and caption
        \input{mPICm08b.pic}
        %\vspace{...} %% controls space between pict and caption
        b. Straight arrows
        \end{center}
\end{minipage}
%} %end of framebox
%---------
\caption{....\hspace{7mm}} % add \hspace{} to adjust horiz possn
\end{center}
\end{figure}
```

## 9 Downloading and installing $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$

$\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ is an excellent small graphics package, freely available from CTAN and the usual $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ CD-ROM discs ${ }^{13}$. Download all the files in the following two directories, and place them where your $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ system can find them ${ }^{14}$.

- CTAN/tex-archive/graphics/pictex/
- CTAN/tex-archive/graphics/pictex/addon/

If you are a ^{A}T_{E}\mathrm{X}\)user,thenuse\usepackage\{pictexwd\}.Ifyouareaplain$\mathrm{T}_{\mathrm{E}}\mathrm{X}$user,thenuse\inputpictexwd.tex(seeSection4.2.1andSection9.2fordetails).undefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefined

Unfortunately, the $\mathrm{P}_{\mathrm{I}} C T \mathrm{EX}$ documentation is not available from CTAN-the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{EX}}$ manual has to be purchased separately (see Section 9.5). However, mathsPIC users will mostly find this unnecessary, since those $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ commands which are particularly useful in conjunction with mathsPIC are described in the mathsPIC manual (Section 6.3), together with examples in the code for the various Figures.

### 9.1 The original files (1986) <br> CTAN/tex-archive/graphics/pictex/

The original $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ package by Michael Wichura (21/09/1987) originally consisted of the 4 files listed below. On the left is the MS-DOS name (truncated to 8 characters), and on the right is the full UNIX name).

The file latexpic.tex gives Plain $T_{E} X$ users the option of using the $\mathrm{I}_{\mathrm{A}} \mathrm{T}_{\mathrm{E}} \mathrm{X}$ Picture macros $\backslash$ line, \vector, \circle, \oval, \thicklines and \thinlines (for syntax and use with $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ see Wichura, 1992).

Note that only two of the files are required for using with plain $\mathrm{T}_{\mathrm{E}} \mathrm{X}$, while three files are required when running $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$.

```
latexpic.tex 11243 bytes (latexpicobjs.tex --for plain TeX only)
prepicte.tex 1293 bytes (prepictex.tex --for LaTeX)
pictex.tex 133388 bytes (pictex.tex --for LaTeX and plain TeX)
postpict.tex 1614 bytes (postpictex.tex --for LaTeX)
```

[^10]The three files required for use with $\mathrm{AT} \mathrm{IEX}_{\mathrm{E}}$ need to be loaded (input) in the order shown above. Note that when using $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ with $\mathrm{IAT}_{\mathrm{E}} \mathrm{X} 2 \varepsilon$ it is necessary to redefine the $\mathrm{IAT}_{\mathrm{E}} \mathrm{X} 2.09$ command $\backslash$ fiverm (because $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ was originally written for $\mathrm{IAT}_{\mathrm{E}} \mathrm{X} 2.09$ ). This is most easily done as follows.
\newcommand\{\fiverm\}\{\rmfamily\tiny\}
Alternatively you can use the more robust method (i.e. for wizards) suggested by Michael J Downes as follows (I believe Michael Downes suggested this originally on the comp.text.tex usenet group-see also the file fntguide.tex among the $\mathrm{L}_{\mathrm{E}} \mathrm{T}_{\mathrm{X}} 2 \varepsilon$ documents).
\declarefixedfont\{\fiverm\}\{\encodingdefault\}\{\rmdefault\}\{m\}\{n\}\{5\}
A significant problem with the original $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ package was that it was very memory hungry. However, in 1994 this problem was overcome by a significant rewrite by Andreas Schrell (see Section 9.2).

### 9.2 The new updated files (1994)

## CTAN/tex-archive/graphics/pictex/addon/

In 1994 Andreas Schrell uploaded a set of updated $\mathrm{P}_{\mathrm{I}} \mathrm{CTEX}_{\mathrm{E}}$ files into the CTAN: . . ./pictex/addon/ directory. One of these additional files (pictexwd.tex) is a replacement for the original (pictex.tex), and is extremely economic in its use of $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ 's dimension registers, allowing significantly better memory usage with exactly the same functionality. The other files correct some errors (piccorr.sty), and add new functionality (picmore.tex).

```
pictexwd.sty 416 bytes
pictexwd.tex 133232 bytes
picmore.tex }2952\mathrm{ bytes
piccorr.sty 4608 bytes
pictex.sty 311 bytes
```

- pictexwd.sty

For ${ }^{A} T_{E} X$ users. This replaces pictex.sty. It inputs prepictex.tex, pictexwd.tex, and postpictex.tex, as well as inputting piccorr.sty and picmore.tex if these are available.

- pictexwd.tex

For $T_{E} X$ users.

- picmore.tex

An extension for drawing impulse diagrams.

- piccorr.sty

A correction for the original $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \betweenarrows command.

- pictex.sty

The $\mathrm{IA}_{\mathrm{E}} \mathrm{X}$ style-option for loading the original $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ files. Note that it also inputs piccorr. sty and picmore.tex if these are available.

All the necessary files required for running $\mathrm{P}_{\mathrm{T}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ are automatically input in the correct order by pictexwd. sty ( $\mathrm{EA}_{\mathrm{E}} \mathrm{X}$ users), or by pictexwd.tex ( $\mathrm{TEX}_{\mathrm{E}} \mathrm{users}$ ). Users of $\mathrm{IA}_{\mathrm{E}} \mathrm{X} 2_{\varepsilon}$ should include the following command in the preamble.

## \usepackage\{pictexwd\}

Users of plain $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ need to include the following.
\input latexpic.tex
\input pictexwd.tex
Note that it is still necessary to download all the original $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ files even when using Andreas Schrell's new files, as some of the original files are still required.

### 9.3 Pictex2.sty

CTAN/tex-archive/macros/latex/contrib/supported/pictex2.sty
16418 bytes 09/05/1999
William Park ${ }^{15}$ has written a style option (pictex2.sty) which adds two useful commands to standard $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$, which force the use of the \putrule command where lines are either horizontal or vertical, thus saving on memory (note that mathsPIC automatically implements the use of \putrule in these circumstances - see Section 4.6). These two commands are as follows.

- \putanyline command

This command invokes the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ \putrule command (instead of $\backslash \mathrm{plot}$ ) in cases where lines are either vertical or horizontal.

- \setanyline command

This is a line-drawing mode (similar to \setlinear) which forces subsequent $\backslash \mathrm{plot}$ commands to invoke $\backslash$ putrule whenever the line is either horizontal or vertical.

### 9.4 Errorbar.tex

CTAN/tex-archive/graphics/pictex/errorbar.tex
3041 bytes 20/04/1988
In 1988 Dirk Grunwald implemented the following errorbar command for $\mathrm{P}_{\mathrm{I}} \mathrm{CT} \mathrm{E}_{\mathrm{E}}$ which draws error bars using a modified $\backslash$ plot command as follows.

- $\backslash$ plotWithErrorBars command

This command, which is case sensitive, has the format

```
\plotWithErrorBars mark M at
    x1 y1 e1
    xn yn en /
```

where $M$ is a $T_{E} X$ character (e.g. \$ $\backslash$ bullet $\$$ ), and $e$ is the size of vertical error bars which are plotted above and below the point. The default cross-bar length is 5 pt, but can be changed, say to 7 pt , using the command $\backslash$ crossbarlength=7pt.
To use this command, input the file errorbar.tex after all the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ files.

### 9.5 The $\mathrm{P}_{\mathbf{I}} \mathrm{CT}_{\mathbf{E}} \mathbf{X}$ Manual

You may wish to purchase The $P_{I} C T_{E} X$ Manual by Michael J. Wichura (The University of Chicago, Chicago, Illinois, USA; wichur@galton.uchicago.edu). This excellent booklet (version 1.1, third printing, March 1992; 85 pages) used to be available from TUG as Publication No. 6 in the TUG TEXniques series. Unfortunately, TUG (http://www.tug.org/) has now stopped publishing the manual, and The $P_{I} C T_{E} X$ Manual is currently only available from Personal $T_{E} X$ Inc. (texsales@pctex.com http://www.pctex.com/) at approximately $\$ 59$ plus postage.

When you buy a copy of the manual you also receive a floppy disk containing $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ files. Unfortunately these are only the original 1986 files, and do not as yet include any of Andreas Schrell's 1994 files.

[^11]
## 10 Bug reports

The author would be grateful for any bug reports, constructive comments, and any ideas for improving this program. The author is grateful to Apostolos Syropoulos, Bob Schumacher, Frantisek Chvala, Orlando Rodriguez, Boris Kuselj, and others for testing this program, and for their many ideas and suggestions.

## 11 Perl version of mathsPIC

A Perl version of mathsPIC is currently in progress (Syropoulos and Nickalls, 2000). It will have a number of enhanced features, particularly with regard to handling of variables. The authors expect it to be first released in the Autumn of 2001.

## 12 History

- 2.1 (November, 2000):

Revised the documentation; fixed numerous bugs; introduced the $\backslash$ and $\backslash_{\sqcup} \ldots$ commands to facilitate the use of $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ and $\mathrm{IAT}_{\mathrm{EX}}$ commands and for copying lines verbatim. The following commands have also been added/extended.

```
drawCurve(ABC)
drawline(AB)[d] %% added the [] option
drawline*(AB) %% disables use of \putrule
point(S){Q, rotate(P, 23 deg)} %% added the rotate() option
pointsymbol(char,lineFreeRadius) %% added the line-free radius option
- 1.9b (May 2000):
```

Fixed a bug associated with the drawAngleArc and drawAngleArrow commands.

- 1.9a (January 2000):

Added the options X and Y to the axes option in the paper command, which allows X and Y axes to be drawn. Also added the option of following any of the axes options by a * which prevents ticks being drawn on that particular axis.

- 1.8 f (October 1999):

Fixed problem with scientific notation; added current loop number indicator; added the following new commands:

```
variable(){area()}
variable(){angle()}
variable(){Xpoint()}
variable(){Ypoint()}
inputfile*()
PointSymbol(default)
```

- 1.7 u (September 1999): First release.

[^12]
[^0]:    ${ }^{1}$ mathsPIC (CTAN:/tex-archive/graphics/pictex/mathspic/) was first presented at the EuroTEX'99 conference in Heidelberg, Germany. It is a free MS-DOS program ( $150 \mathrm{~KB} \mathrm{)} \mathrm{compatible} \mathrm{with} \mathrm{MS-Windows} \mathrm{9x}, \mathrm{2000}, \mathrm{NT}$.
    ${ }^{2}$ CTAN:/tex-archive/graphics/pictex/addon/. The files input using pictexwd.sty total only 138 KB. See Section 9 for details.

[^1]:    ${ }^{3}$ The EmTEX screen viewer is dviscrs.exe and is usually called via the batch-file vs.bat.

[^2]:    ${ }^{4}$ See Section 9.5 for information regarding the $\mathrm{P}_{\mathrm{T}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ manual.

[^3]:    ${ }^{5}$ Since $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ uses the name 'axis', mathsPIC recognises both spellings ('axis' and 'axes').

[^4]:    ${ }^{6}$ These are described in Chapter 10 of the The $T_{E} X b o o k$ by D. Knuth.

[^5]:    ${ }^{7}$ See Harald Harders' useful file (textcomp.tex) which shows the characters of the textcomp font together with their names. It can be found at CTAN:/tex-archive/info/texcomp-info/.

[^6]:    ${ }^{8}$ Note that the $\mathrm{P}_{\mathrm{I}} \mathrm{CTE}_{\mathrm{E}} \mathrm{X} \backslash$ putrule command employs the $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ and $\mathrm{LAT}_{\mathrm{E}} \mathrm{X} \backslash$ rule command, and so is only used for horizontal and vertical lines.

[^7]:    ${ }^{9}$ Hoenig A (1998). $T_{E} X$ Unbound: $L^{A} T_{E} X$ and $T_{E} X$ strategies for fonts, graphics, \& more. (Oxford University Press, UK) pp 580. ISBN: 0-19-509685-1 (hardback), 0-19-509686-X (paperback); see pages 377-389.

[^8]:    ${ }^{10}$ See the $\mathrm{P}_{\mathrm{I}} \mathrm{CT}_{\mathrm{E}} \mathrm{X}$ manual (Wichura, 1992).

[^9]:    ${ }^{11}$ Figure 16 was constructed and drawn by Frantisek Chvala.
    ${ }^{12}$ see The Metafont book by DE Knuth, chapter 3 for details regarding Bezier curves.

[^10]:    ${ }^{13}$ Available from $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ user groups. Note that a particularly good 3-disk CTAN archive is published annually by the German $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ users group DANTE (dante@dante.de, http://www.dante.de).
    ${ }^{14}$ For EmTeX, this would be the directory $\mathrm{c}: \backslash \mathrm{emtex} \backslash$ texinput $\backslash$ pictex $\backslash$

[^11]:    ${ }^{15}$ parkw@better.net

[^12]:    ${ }^{16}$ The editor is Apostolos Syropoulos (email: apostolo@obelix.ee.duth.gr).
